Reading Discussion

- **Tidy Data**

By Hadley Wickham

Tidy Data:

1) Structure: Most statistical datasets are rectangular tables made up of *rows* and *columns*
2) Definition: A dataset is a collection of values, usually either numbers (if quantitative) or strings (if qualitative).
3) Values are organized in two ways. Every value belongs to a *variable* and an *observation.*

Example

person	treatment	result
John Smith	a	—
Jane Doe	a	16
Mary Johnson	a	3
John Smith	b	2
Jane Doe	b	11
Mary Johnson	b	1

Variables in columns and observations in rows

Therefore, in tidy data:

- Each variable forms a column.
- Each observation forms a row.
- Each type of observational unit forms a table.

The five most common issues with messy datasets

- Column headers are values, not variable names.
- Multiple variables are stored in one column.
- Variables are stored in both rows and columns.
- Multiple types of observational units are stored in the same table.
- A single observational unit is stored in multiple tables.

Column headers are values, not variable names

row	a	b	c
A	1	4	7
B	2	5	8
C	3	6	9

(a) Raw data

row	column	value
A	a	1
B	a	2
C	a	3
A	b	4
B	b	5
C	b	6
A	c	7
B	c	8
C	c	9

(b) Molten data

Table 5: A simple example of melting. (a) is melted with one colvar, row, yielding the molten dataset (b). The information in each table is exactly the same, just stored in a different way.

(b) Tidy data

Table 10: Tidying the TB dataset requires first melting, and then splitting the `column` column into two variables: `sex` and `age`.

Variables are stored in both rows and columns
